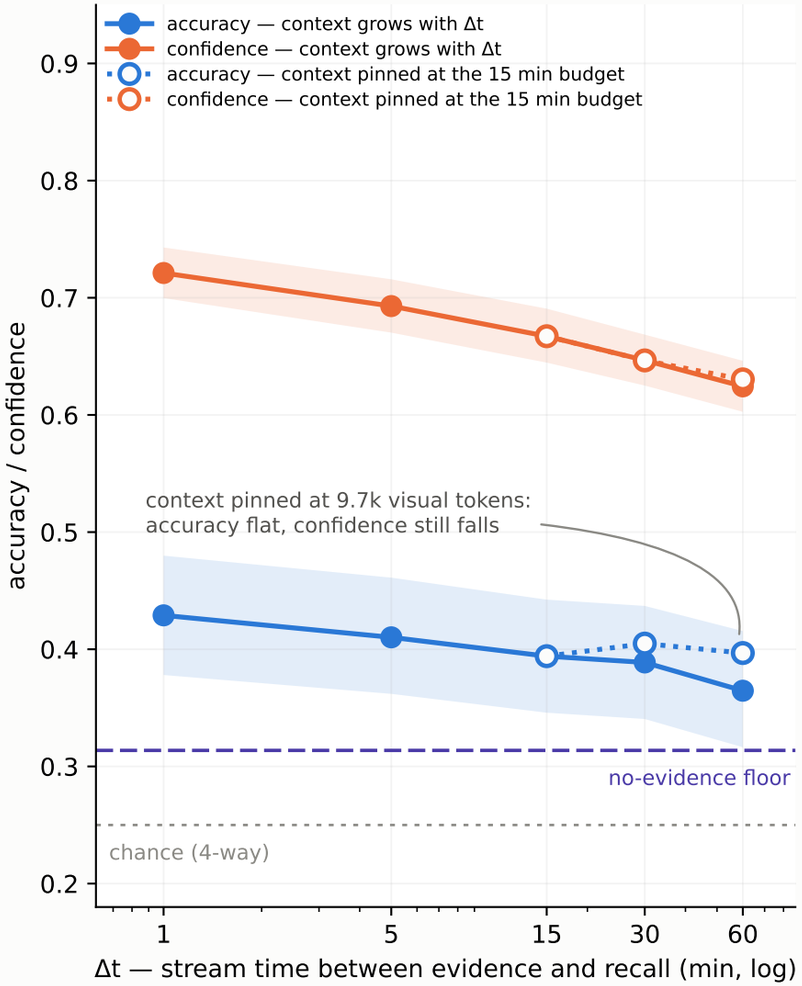
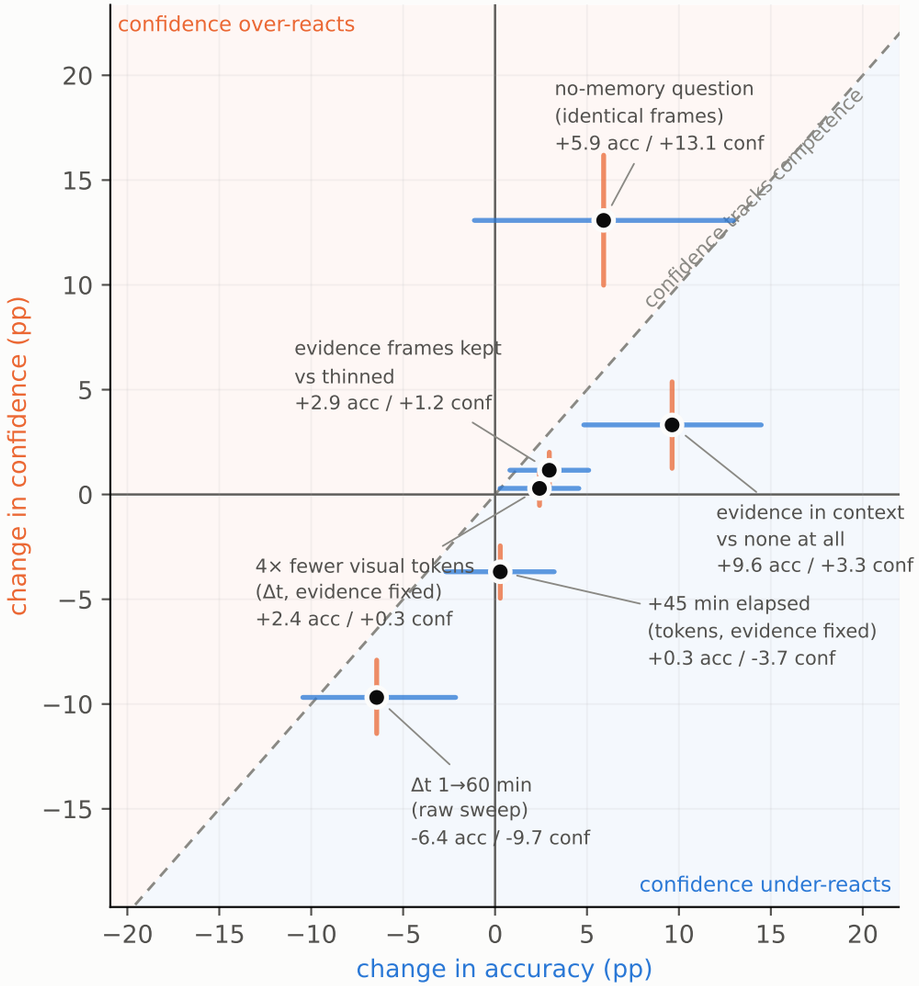
Confidence tracks the wrong variable

+45 min of elapsed time at fixed context costs +0.3 pp accuracy but -3.7 pp confidence;
4× the context at fixed Δt costs -2.4 pp accuracy but -0.3 pp confidence;
having the evidence at all is worth +9.6 pp accuracy but +3.3 pp confidence (n=373 questions, paired, cluster-bootstrapped)

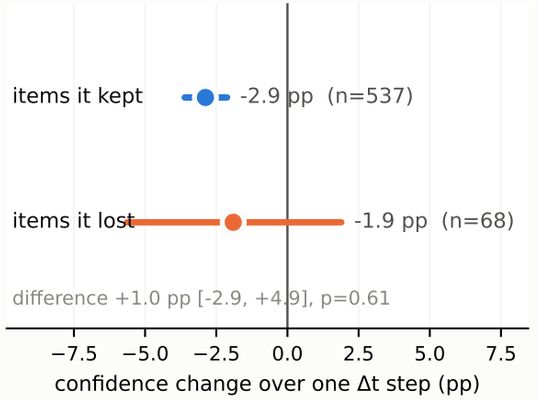
A Pin the context length and the accuracy decline goes away — the confidence decline does not

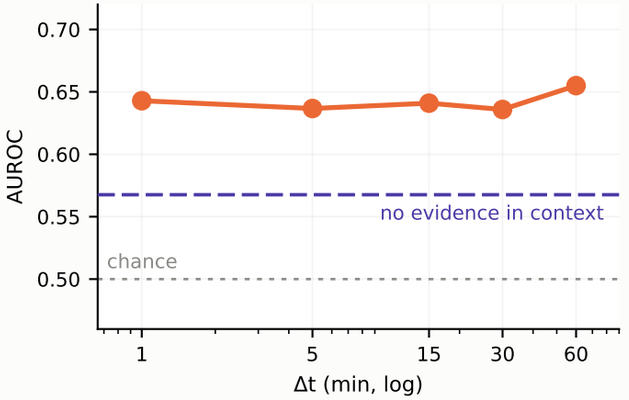


B What each manipulation moves — 95% CIs, horizontal for accuracy, vertical for confidence



C The drop lands on everything, not on the items actually lost





…while the ranking is untouched by Δt — it is only the level that slides
